

Lecture 1:

Diagrams as syntax

Part 1: Introduction

What is "applied category theory"?

The name is sociological —

invented in 2018 to refer to a cluster
of existing related ideas.

— it's not an accurate name!

It is interested in processes and
systems with a focus on
compositionality (CS, physics/engineering, bio.)

modelled often with symmetric monoidal
categories, operads + other things that
have syntax in diagrams.

In my view - "real" ACT is actually applied —
the trick is to know when to stop
doing category theory and do some
honest work.

But this course is about theory —
ideas that have proven useful for
thinking about applications.
(but I'd be less pedantic than a
typical category theorist)

This course will be relatively
broad + shallow — but focus on
commonly recurring structures.

Part 2 : String diagrams

Definition

A monoidal signature Σ

consists of :

1. A set $\text{Ob}(\Sigma)$ of object symbols
2. A set $\text{Mor}(\Sigma)$ of morphism symbols
3. Functions $s, t : \text{Mor}(\Sigma) \rightarrow \text{Ob}(\Sigma)$
(source, target)

X^* = set of finite lists on X

Idea: we think of the list x_1, \dots, x_n as a formal tensor product $x_1 \otimes \dots \otimes x_n$

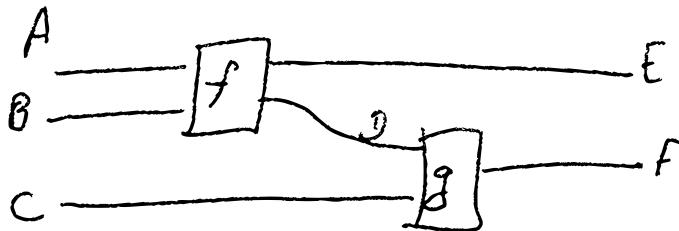

Cf. signatures in logic, Lawvere theories &c.

Note: Monoidal signatures could be called "directed hypergraphs" but it's ambiguous.

Also it's an ordered version of Petri nets.

A string diagram looks like this:

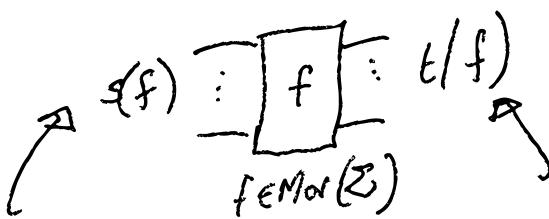

strings/wires
boxes/nodes

[Note: this is left-to-right orientation.
Top-to-bottom and bottom-to-top are
also in common use].

A string diagram on the signature Σ has:

- strings labelled by object symbols $\in \mathcal{O}(\Sigma)$
- boxes labelled by morphism symbols $\in \text{Mor}(\Sigma)$
- "local connectivity" like this:

wires listed in bottom-to-top order

If wires do not cross we say the string diagram is planar.
 In this course we will allow wires to cross.

[Looking ahead: monoidal vs. symmetric monoidal]

But: The order of connectivity at boxes + diagram boundaries is still important. So:

For now, we do not allow wires to change direction:

A string diagram with this restriction is called progressive.

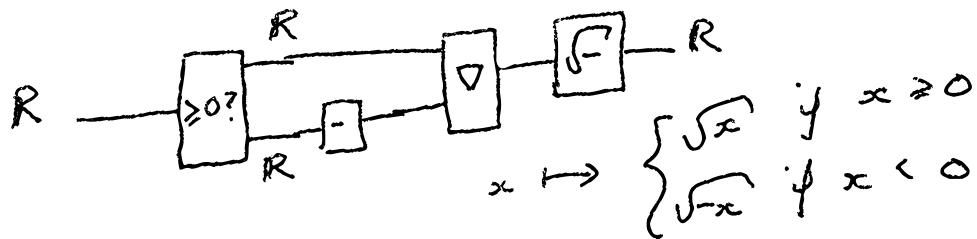

It's a sort of causality condition.

Some monoidal categories of interest

- $(\underline{\text{Set}}, \times)$ i.e. total + deterministic functions
in a cartesian "wave-style" world

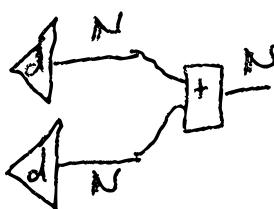

- $(\text{Set}, +)$ functions in a "particle-style" world

- $(\text{Kl}(M), \otimes)$ where M is a commutative monad on Set i.e. $\text{do}\{x \leftarrow a; y \leftarrow b;\} = \text{do}\{y \leftarrow b; x \leftarrow a;\}$
 $\text{pure}\{x, y\} = \text{pure}\{y, x\}$

If M is not commutative then $\text{Kl}(M)$ is not monoidal, only premonoidal — possible but annoying to handle

- Let Δ^X = set of (finite support) probability distributions on X .
Then $\text{Rel}(\Delta)$ looks like this:

$$d: \mathbb{I} \rightarrow \Delta^N, \\ d(*) = \frac{1}{6}|1\rangle + \dots + \frac{1}{6}|6\rangle$$

$d+d: \mathbb{I} \rightarrow \Delta^N$, $d(*)$ = distribution on sum of 2 dice (i.e. binomial)

This is the prototypical example of
a Markov category

- Examples will come back to:
linear maps, relations*, spans, cospans
Each of these has a biproduct \oplus
arising from $+$, and a tensor product
 \otimes arising from \times .
* $\text{Rel} = \text{Rel}(\mathbb{P})$ - need to be a bit careful constructively.

Theorem [Tajan - Street coherence theorem]

let Σ be a monoidal signature,

let \mathcal{C} be a symmetric monoidal category.

Fix an interpretation of Σ in \mathcal{C} , i.e.

$$[-]: \text{ob}(\Sigma) \rightarrow \text{ob}(\mathcal{C})$$

$$[-]: \text{Mor}(\Sigma) \rightarrow \text{Mor}(\mathcal{C})$$

$$\text{s.t. if } s(f) = x_1, \dots, x_m, t(f) = y_1, \dots, y_n$$

$$\text{then } [-f]: x_1 \otimes \dots \otimes x_m \rightarrow y_1 \otimes \dots \otimes y_n$$

[Note: if \mathcal{C} is not strict monoidal then we have to pick a consistent bracketing].

Then $[-]$ can be uniquely extended

to string diagrams,

and is isotopy invariant.

- i.e. only connectivity matters.

$$[A \longrightarrow A] = \text{id}_{\text{FAD}}$$

$$[\begin{array}{|c|c|} \hline f & \\ \hline \end{array}] = [f]$$

$$[\begin{array}{|c|c|c|} \hline f & g & \\ \hline \end{array}] = [\begin{array}{|c|} \hline f \\ \hline \end{array}] ; [\begin{array}{|c|} \hline g \\ \hline \end{array}]$$

$$[\begin{array}{|c|c|} \hline f & g \\ \hline \end{array}] = [\begin{array}{|c|} \hline f \\ \hline \end{array}] \otimes [\begin{array}{|c|} \hline g \\ \hline \end{array}]$$

* When \mathcal{C} is not strict,
this case
needs more
care

Fundamental not-a-theorem of ACT:

Everybody understands the Joyal-Street theorem instinctively!

You can teach it to a 5-year-old

You can teach it to a management consultant

etc.

It's completely intuitive but also
completely formal.

The J-S theorem in mathematical context

Then [J-S, slick version]

Let Σ be a monoidal signature.

Then the free [-, braided, symmetric] monoidal category on Σ is equivalent to the category whose morphisms are planar progressive string diagrams modulo [2d, 3d, 4d] ambient isotopy.

Compare: Let X be a set. Then the following monoids are isomorphic:

1. The free monoid on X

2. The monoid X^* "1d string diagrams"

3. The monoid of "2d string diagrams"

modulo 1d isotopy.

And mod 2d isotopy is the free commutative monoid = bags!

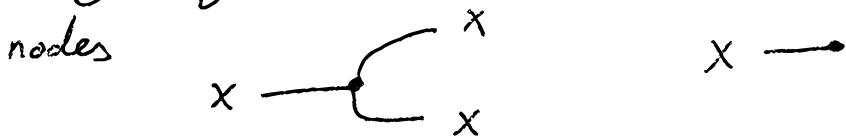

Keywords for more in this direction :

- (1) Periodic table of k -tuply monoidal
 n -categories
- (2) Cobordism hypothesis .

3. Copying and deleting

on $x \in \text{ob}(\Sigma)$

A (commutative) comonoid in a string diagram means distinguished nodes

which satisfy

Three string diagram equations illustrating the properties of the comonoid structure:

- The first equation shows the commutativity of copying: $x \rightarrow x = x \rightarrow x$. It consists of two horizontal lines, each ending in a node. The top line has a loop that crosses over the bottom line. The bottom line has a loop that crosses under the top line. Both configurations are shown to be equal.
- The second equation shows the associativity of copying: $x \rightarrow x = x \rightarrow x$. It consists of three horizontal lines. The leftmost line ends in a node with two loops, one above the other. The middle line ends in a node with two loops, one above the other. The rightmost line ends in a node with two loops, one above the other. All three configurations are shown to be equal.
- The third equation shows the identity of the deletion operation: $x = x$. It consists of a single horizontal line ending in a node with two loops, one above the other. This configuration is shown to be equal to itself.

i.e. we identify string diagrams up to
these equations
& require all interpretations satisfy it.

Alternative definition : we have a family of distinguished nodes

satisfying

A node connected to two lines. One line has a label n above it, and the other has a label k above it. An equals sign follows, and then there is another diagram of a node connected to two lines, with a bracket below it labeled $n+k-1$.

Examples (lots more in the next 2 lectures)

- In (Set, \times) or any cartesian monoidal cat we have copy maps

$$\Delta: X \rightarrow X \times X, \quad x \mapsto (x, x)$$

from the universal property

A commutative triangle with nodes X , $X \times X$, and X . The top arrow is labeled Δ , the left arrow π_1 , and the right arrow π_2 .

- We can lift that to $(\text{Rel}(M), \otimes)$ by

$$X \xrightarrow{\Delta} X \times X \xrightarrow{P_{X \times X}} M(X \times X)$$

This still satisfies the axioms.

E.g. in $\text{Rel} = \text{Rel}(P)$, $\Delta: X \mapsto X \otimes X$,

$$x, \Delta(x_2, x_3) \text{ iff } x_1 = x_2 = x_3.$$

A supply of comonoids in a monoidal category is a choice of (commutative) comonoid on every object satisfying:

$$x \otimes y \xrightarrow{x \otimes f} x \otimes y = x \xrightarrow{x} x \quad \text{and} \quad x \otimes y \xrightarrow{f \otimes y} x \otimes y = y \xrightarrow{y} y$$

$$x \otimes y \longrightarrow = x \longrightarrow$$

$$I \longrightarrow = \boxed{\quad} \quad I \xrightarrow{I = \boxed{\quad}} \boxed{\quad} = id_I$$

We call a morphism $x \xrightarrow{f} y$ deterministic if it is a homomorphism of comonoids:

$$x \xrightarrow{\boxed{f}} y = x \longrightarrow$$

$$x \xrightarrow{\boxed{f}} y = x \xrightarrow{\boxed{f}} y$$

This characterises pure functions!

[Small exercise: \longrightarrow and $\xrightarrow{\quad}$ are always deterministic].

Example In $\text{Kl}(1)$,
 $\text{coin} : \{1\} \rightarrow \{\text{H}, \text{T}\}$, $\text{coin} = \frac{1}{2} |\text{H}\rangle + \frac{1}{2} |\text{T}\rangle$.

is not deterministic.

$$\begin{array}{c} \text{coin} \\ \swarrow \quad \searrow \end{array} \left. \begin{array}{c} \{\text{H}, \text{T}\} \\ \{\text{H}, \text{T}\} \end{array} \right\} = \frac{1}{2} |(\text{H}, \text{H})\rangle + \frac{1}{2} |(\text{T}, \text{T})\rangle$$

\neq

$$\begin{array}{c} \text{coin} \\ \swarrow \quad \searrow \end{array} \left. \begin{array}{c} \{\text{H}, \text{T}\} \\ \{\text{H}, \text{T}\} \end{array} \right\} = \frac{1}{4} |(\text{H}, \text{H})\rangle + \frac{1}{4} |(\text{H}, \text{T})\rangle + \frac{1}{4} |(\text{T}, \text{H})\rangle + \frac{1}{4} |(\text{T}, \text{T})\rangle$$

My favourite result in category theory :

Theorem [Fox]

Let C be a SMC. Then TFAE :

- (1) C admits a supply of commutative comonoids such that all morphisms are deterministic
- (2) C is cartesian monoidal.

This says we can characterise a universal structure in a purely graphical way !

Side-line: for any SMC C there is a category $\text{Comon}(C)$ of comonoids + homomorphisms in C .
 $\text{Comon}(C)$ is cartesian, + is the cofree cartesian cat on C .

Also : $(\text{Comon}(\text{Kl}(M)))$ recovers the base category of M].

In a cartesian monoidal category,
wlog we can only consider morphism
generators with 1 output, because

$$A \xrightarrow{f} C = A \xrightarrow{\quad} \begin{cases} f \\ f \end{cases} \xrightarrow{\quad} \begin{cases} B \\ C \end{cases}$$

$$= A \xrightarrow{\quad} \begin{cases} f_1 \\ f_2 \end{cases} \xrightarrow{\quad} \begin{cases} B \\ C \end{cases}$$

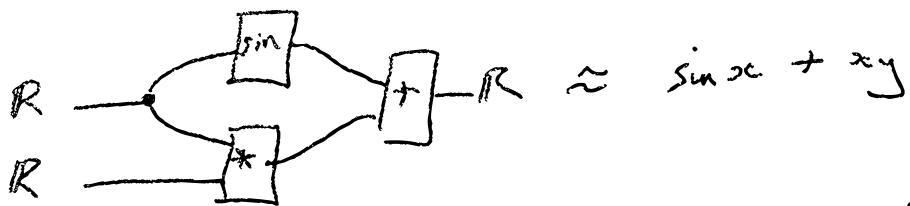

Now graphical syntax is equivalently
expressive as traditional term syntax:

$$\boxed{f} \approx f(x_1, \dots, x_n)$$

And copying says we can use variables
multiple times:

$$\overbrace{\quad}^2 \boxed{f} \approx f(x, x)$$

A term written graphically is called a computational graph.

They're used in deep learning / differentiable programming — more in lecture 4.

A Markov category is a SMC +

Supply of commutative comonoids,

satisfying $\dashv \vdash f = \dashv$

for all morphisms f .

Ex. $\text{Kl}(\Delta)$ is a Markov category.

Idea: This is the prototypical one,

they are a good axiomatic formulation
for probability.
